

## COSC 39: Theory of Computation

### Problem 1. Parsing regular expressions.

Can the task of parsing regular expressions itself be implemented using a regular expression? This property is known as universality—the language is powerful enough to recognize its own structure.

We can treat the collection of regular expressions itself as a language  $\text{RegExp}$ , containing words that are valid regular expressions over the binary alphabet  $\{0, 1\}$ . To write down a regular expression in  $\text{RegExp}$ , in addition to 0 and 1 we need a few extra symbols; so we define the alphabet set for  $\text{RegExp}$  to be

$$\Sigma' := \{0, 1, +, *, (, )\}.$$

- (a) Prove that the language  $\text{RegExp}$  itself is not regular. In other words, we cannot construct a parser for valid regular expressions using only DFAs/NFAs.
- (b) What if we disallow nested parentheses? (In other words, inside a pair of parentheses ( and ), no further parentheses can appear.) Prove or disprove that the language  $\text{RegExp}$  with no-nesting constraint is regular.

### Problem 2. Regular or not?

Prove or disprove that each of the languages below is regular (or not). Let  $\Sigma^+$  denote the set of all nonempty strings over alphabet  $\Sigma$ ; in other words,

$$\Sigma^+ = \Sigma \cdot \Sigma^*.$$

(a)

$$\{wxw^R : w, x \in \Sigma^+\}$$

(b)

$$\{ww^Rx : w, x \in \Sigma^+\}$$

**Hint:** To prove that a language  $L$  is regular, construct an NFA that recognizes  $L$ ; to disprove that  $L$  is regular, construct a fooling set and argue that the construction is correct.
